

For Group Question 3.1:

I do think it's partially an exciting idea to have a chip implanted in our brains. This will enable us to constantly connect with our friends and family without having to constantly look over our phones or computers to see if they sent us messages or posted something new that happened to them on social media. We will instantly be updated as to what they are doing in real-time. In addition, since the implant will help increase our memory capacity with gigabytes of data, we will be able to store more information and process information at a quicker rate which will also make learning new skills easier. We can also store memories of our most cherished experiences and relive those same specific memories if we want to, anytime and from anywhere. Another thing to relate to is having access to a search engine like Google with just our mere thought. This added feature will help us stay informed with the most current information and would make us more globally connected than ever before, bringing a huge impact on how businesses, governments, healthcare, countries, and in general people communicate with one another. An example of brain implants, or brain-computer interfaces is through the company Neuralink which was founded by Elon Musk. They have begun making and testing their brain implants, mostly for people who are paralyzed. This is beneficial for those disabled, those who can't write or speak, because it will enable them to properly communicate with other people by allowing them to control devices such as mobile phones or computers to send messages based on their thoughts.

However, there are valid points as to why this idea is also dangerous. This can range from our data or activity history being much easier to collect and track by companies or the government, our brain implants having the potential to be hacked by anyone, the brain implant becoming corrupted therefore bringing harm to us, and there is also the potential risk that once we do have the chip implanted in our brain, that we will no longer be ourselves such as that we won't be fully human anymore but be part machine. That is a scary thought.

Overall, while the idea of having a brain implant might seem thrilling, there are also potential risks that arise when we decide to get such a technology.
